

Instructions for HackAlem AI Participants

1. **Activate access to Codex, OpenAI API, and NVIDIA.** Instructions can be found in the **OpenAI and NVIDIA Activation for HackAlem AI Participants** file. Do not publish API keys on GitHub.
2. Select **one case**. Solving all cases in the track is not required.
3. Review the case requirements and evaluation criteria.
4. Discuss implementation with your team, assign roles and tasks.
5. Select a workflow:
 - **Via the Codex app:** connect your GitHub account to Codex, grant access to the working folder (the team repository created by the platform), assign tasks via prompts.
 - **Via Visual Studio Code:** install the Codex extension, log into your account, open the team repository, develop the solution, and push the code to GitHub.
 - You can use **any other development method**. The main thing is to use an **AI agent and host the final code in the team's GitHub repository** provided by the hackathon platform.
6. Implement the mandatory case requirements within 5 hours and test the main flow from input data to output.
7. Prepare the README. Specify:
 - what the project does;
 - what has been implemented;
 - technologies used and architecture;
 - installation and launch instructions;
 - testing example;
 - data used and external services;
 - known limitations;
 - link to the deployed version, if available.
8. To prepare the README, you can use the organizer's prompt from the case document, generate it, and insert it via Codex.
9. Push the latest version of the project to the team's GitHub repository.

10. Go to the tracks page, select your case, and click "**Submit Solution**". Fill in the project name and description. The solution can be updated until the hackathon deadline. Video tutorial: <https://youtu.be/qFA0tuMcKPg?si=D79MC3XyGdPsEkKo>

README prompt:

Participants can simply paste this prompt into Codex:

"Analyze the current project and create a complete README.md file in English.

The README should be clear and easy for the hackathon judges to understand and should include:

1. Project name
2. Short description — what problem the project solves and who it is designed for.
3. What has been implemented — the main features and capabilities of the solution.
4. How the solution works — briefly describe the main user flow from input data to the final result.
5. Technologies — programming languages, frameworks, libraries, AI models, APIs, and external services used.
6. Project architecture — the main components and how they interact with each other.
7. Installation and launch — step-by-step setup instructions with the required commands.
8. How to test the solution — provide an example scenario that the judges can reproduce.
9. Data and integrations — specify the data sources, APIs, and external services used.
10. Limitations — explain what has not been implemented or what limitations the current version has.
11. Link to the deployed version, if available.

Use only information that can be verified from the current repository. Do not invent features, technologies, or results that are not actually present in the project. Format the README cleanly in Markdown."
